SUMMARY

- Arrays in PHP is a type of data structure that allows us to store multiple elements of similar data type under a single variable thereby saving us the effort of creating a different variable for every data.
- The arrays are helpful to create a list of elements of similar types, which can be accessed using their index or key.
- PHP internally stores all arrays as associative arrays; the only difference between associative and indexed arrays is what the keys happen to be.
- The array's values are copied into the listed variables in the array's internal order.
- The array_slice() function returns a new array consisting of a consecutive series of values from the original array.
- The function returns a Boolean value that indicates whether the first argument is a valid key in the array given as the second argument.
