SUMMARY

- In PHP, Object is a compound data type (along with arrays). Values of more than one types can be stored together in a single variable.
- In object oriented programming, a class is a definition of an object, whereas an object is an instance of an object, meaning that from one class you can create many objects.
- In object-oriented terminology, characteristics of an object are called properties.
- To create a method for a class you use the function keyword followed by the name and parentheses.
- To design your program or code library in an object-oriented fashion, you will need to define your own classes, using the class keyword.
- A constructor is a function with the same name as the class in which it is defined.
- Property declarations are optional and are simply a courtesy to whoever maintains your program.
- A class definition includes the class name and the properties and methods of the class.
