many requirements documents for Web applications that are essentially **data warehouses**. Approach has been to dedicate a section to each of the major data entities. A project management application might have a collection of project descriptions, a collection of users, and a collection of comments. Each of these would have a section in the functional requirements that lists first all the information they store and then the ways the information can be manipulated.

Keyword

Data warehouse is a type of data management system that is designed to enable and support business intelligence (BI) activities, especially analytics

The performance requirements are constraints on the functionality. You may wish to outline a minimum browser configuration for use of the site. Maximum page weights are a good idea. If the client is dictating that a certain technology be used, it. It's good to know in advance that while you will be allowed to use PHP, you have to deal with Oracle and Internet Information Server on Windows NT.

The exception-handling describes how the system deals with adversity. The two parts of this are disaster and invalid input. Discuss what should happen if the Web server suddenly bursts into flame. Decide whether backups will be made hourly, daily, or weekly. Also decide how the system handles users entering garbage. For example, define whether filling out a form with a missing city asks the user to hit the back button or automatically redisplays the form with everything filled out and the missing field marked with a red asterisk.

If the client has a preference for the order of implementation, outline it. Our experience has been that, faced with a dire deadline before the project begins, the client will bargain for which functionality will appear in the first round. Other requirements may not be critical to the system, and the client is willing to wait. If there is a preference in this area, it is very important for the designer and implementers to know in advance.

Farther in the future are the foreseeable modifications. The client may not be ready to create a million-dollar e-commerce site just yet, but they may expect to ask you to plug this functionality into the site a year from now. It may not make sense to use an expensive database to implement a 50-item catalog, but building a strong foundation for later expansion will likely be worthwhile.

The last part of the requirements specification is a collection of design hints. This represents the requirements
