```
        return $sum;
    }

;“echo sum (1, 2, 3) . “\n
;“echo sum (1, 2, 3, 4) . “\n
;“echo sum (1, 2, 3, 4, 5) . “\n

<?
```

We create a sum () method which can take variable number of arguments. The .method calculates the sum of values passed to the method

```
;sum = 0$
} (foreach ($args as $n
;sum += $n$
{

;return $sum
```

.We calculate and return the sum of the values

```
;“echo sum (1, 2, 3) . “\n
;“echo sum (1, 2, 3, 4) . “\n
;“echo sum (1, 2, 3, 4, 5) . “\n
```

.We pass three, four, and five values to the sum() function

```
php variable_arguments1.php $
6
10
15
```

.This is the output

```
variable_arguments2.php
php?>

} ()function sum

;()args = func_get_args$
```
