In this example, we have two variables with the same name. They do not collide because they exist in different scopes.

```
$ php scope2.php
3
4
```

The value is 3 inside the function and 4 outside the function.

In the next example, we will modify a value inside the function.

scope3.php

```
<?php

$value = 1;
function simple() {

    global $value;
    $value = 2;
}

echo $value, "\n";
simple();
echo $value, "\n";

?>
```

We use the global keyword to reference a variable defined outside the body of the function.

```
$ php scope3.php
1
2
```

The $value was successfully modified inside the simple () function.

In this part of the PHP tutorial, we covered PHP functions.

3.2 CPU USAGE INFORMATION

We are going to utilize the getrusage() function. Keep in mind that this is not available on Windows platforms.
