```php
namespace App\Http\Requests;

class StoreTransactionReportRequest extends FormRequest
{
  public function rules(): array
  {
    return [
      'start_date' => ['required', 'date'],
      'end_date' => ['required', 'date'],
    ];
  }

  public function interval(): DateInterval
  {
    return DateInterval::make(
      StartDate::fromString($this->start_date),
      EndDate::fromString($this->end_date),
    );
  }
}
```

The endpoint accepts `start_date` and `end_date` parameters but it creates a `DateInterval` value object from these values and the whole application works with this object instead of string values. The `DateInterval` is really simple:

```php
namespace App\ValueObjects;

class DateInterval
{
  public function __construct(
    public readonly StartDate $startDate,
    public readonly EndDate $endDate,
  ) {}

  public static function make(StartDate $startDate, EndDate $endDate): self
  {
```
