That last one should really only be created by another program. Here's an illegal variable declaration and the resulting error:

```
$4 = 4; // illegal, starts with a number
```

```
Output:
Parse error: syntax error, unexpected integer "4", expecting variable or
"{" or "$"
```

Finally, variable names are case sensitive, as the following code demonstrates:

```
$variable = 'some text';
echo $vArIaBLe . PHP_EOL;
```

```
Output:
Warning: Undefined variable $vArIaBLe
```

Assigning Values and Types

Remember that earlier in the chapter, we examined the dynamic nature of PHP's data typing system? I mentioned that a variable's type is determined when its value is assigned, so let's look at that in more detail.

Scalar Types

```
$myString = "a string";
$myNumericString = "1";
$myInt = 1;
$myFloat = 1.1;
$myBool = true;
$myNull = null;

var_dump($myString);
var_dump($myNumericString);
var_dump($myInt);
var_dump($myFloat);
var_dump($myBool);
var_dump($myNull);
```
