```
Output:
>string(8) "a string"
>string(1) "1"
>int(1)
>float(1.1)
>bool(true)
>NULL
```

When the PHP interpreter encounters a single-quote or double-quote character, it chooses the `string` data type for the variable `$myString`, even if the contents of the string are purely numerical, as in `$myNumericalString`. Similarly, the presence of a decimal point in the assignment of the literal number `1.1` to `$myFloat` means that the type has to be `float`; a non-decimal number will always be assigned as an `int`. Finally, `true` (or `false`) can only mean a boolean type, and `null` is `null` – this scalar type has only one possible value.

Compound Types

```
$myArray = [1, "two", true];
$myObj = new stdClass();

var_dump($myArray);
var_dump($myObj);

Output:
array(3) {
  [0]=>
  int(1)
  [1]=>
  string(3) "two"
  [2]=>
  bool(true)
}
object(stdClass)#1 (0) {
}
```
