```
function foo($bar) {}

/*
 * 'bar' is the argument. When the body of foo() executes
 * this value is assigned to the $bar parameter
 */
foo('bar');
```

Returning

Returning data from a function means that when control returns to the calling code the place where the function is called now has a value. This is achieved using the `return` keyword within the function body wherever you wish the function to finish execution, together with whatever expression is required to define the returned value. It is also possible for a `return` statement to return no value at all (more on this later).

```
$str = 'hello';

write('hello');
write($str);
print glue('hello', 'again');

function write($in)
{
    print "{$in}" . PHP_EOL;
}

function glue($start, $end)
{
    return "{$start} {$end}"  . PHP_EOL;
}

Output:
hello
hello
hello again
```
