```
function getPi(): float
{
    return '3.14159265'; // can cast to a float so also valid
}

function getNow(): DateTime // function returns an instance of this class.
{
    return new DateTime('now');
}

function getMorePi(): float
{
    return 'Three point one four etc. etc.'; // Throws a TypeError
}
```

Be careful when using strict mode:

```
declare(strict_types=1);

function getPi(): float
{
    return '3.14159265'; // is not a float, strict mode is on, TypeError
}
```

To define types for parameters, you place the type's keyword inside the parentheses just before the corresponding variable name like this: `function mungeArray(array $array)`. The following code demonstrates type declarations for function arguments:

```
function increment(int $num): int {
    var_dump($num);
    return $num + 1;
}

print increment('2') . PHP_EOL;

Output:
int(2)
3
```
