```
Output:
integer
```

`match` "cases" can also be expressions, rather than values, which allow for more flexibility. Here's a form that uses logical comparison expressions:

```
$var = 42;
print match (true) {
    $var < 10 => 'low',
    $var === 42 => 'Life the universe and everything',
    $var < 100 => 'high',
};
```

```
Output:
Life the universe and everything
```

Notice how the expressions are tested in order, and the first true result is returned. In this case, `$var` is both equal to *42* and less than *100*, but it's the test for `$var === 42` that is executed first, and `match` does not fall through like a `switch` construct would.

Repetition

PHP offers the same structures for repeating code blocks as most other C-style languages.

for, foreach

Chapter 5, "Array" (in the section "Iteration"), has already explained these two constructs in detail, where it made the most contextual sense. After all, these are structures intended to iterate arrays or array-like data structures. Here's a quick recap of what they look like:

```
$rogueAgents = [
    'Aaron Keener',
    'Theo Parnell',
    'Alani Kelso',
];
```
