```
    ['duck', 'nuke'],
    ['duck'],
];

foreach ($multiArr as $k => $arr) {
    foreach ($arr as $val) {
        switch ($val) {
            case 'duck':
                print "duck from subArr {$k}" . PHP_EOL;
                break;
            case 'goose':
                print "found a goose moving to subArr ". $k + 1 . PHP_EOL;
                break 2;
            case 'nuke':
                print "BOOM! No more game." . PHP_EOL;
                break 3;
        }
    }
}

Output:
duck from subArr 0
duck from subArr 0
duck from subArr 1
found a goose moving to subArr 2
duck from subArr 2
BOOM! No more game.
```

The key to this example is knowing that there are three levels of nesting. An outer `foreach` iterates `$multiArr`, an inner `foreach` iterates each sub-array of `$multiArr`, and the `switch` structure. Each `case` statement inside the `switch` block has a `break` statement. The elements of `$subArr` are strings: `'duck'` triggers a single-level break (terminating the `switch`), `'goose'` has a `break 2`, which terminates two levels of nesting (the `switch` and the inner `foreach`), and `'nuke'` has `break 3`, which terminates everything. As we can see from the output, once `'nuke'` is reached, it's game over, man.
