There also exists the keyword `continue`, which is similar, though its effect is slightly different: it will stop the execution of the current iteration and begin a new one:

```
$arr = ['duck', 'duck', 'duck', 'goose', 'duck'];

$count = 0;
foreach ($arr as $val) {
    $count++;
    if ($val === 'duck') {
        continue;
    }
    print "Found a goose!" . PHP_EOL;
}
print "Visited {$count} elements.";

Output:
Found a goose!
Visited 5 elements.
```

Hopefully the above makes sense: the code in the `foreach` block terminates and begins a new iteration every time it hits `continue`, which is why we only see `'Found a goose!'` once. The point of `$count` is to simply prove that we iterated every element of `$arr`.

Miscellaneous

There are other language constructs that influence the flow of control but are specialized to certain tasks and not used to implement program logic as such (or at least they generally shouldn't, with a few exceptions). These are
