Table 4-1. *Other control constructs*

`declare`	Sets directives, such as `declare(strict_types=1)`
`return`	Terminates a function, optionally passing back data
`include`	Read in a PHP source code file, the contents are executed immediately
`require`	Read and execute a PHP file, throws an error if the file isn't found
`include_once`	Like `include` but can only run once (repeats have no effect)
`require_once`	The `require` form of `include_once`
`die` `exit`	Terminate the program immediately
`goto`	No. Just don't. Not ever.

As noted in an earlier chapter, `exit` (aliased by `die`) are language constructs until PHP 8.4, where they became proper functions with special handling/parsing rules to support the construct-like syntax of calling them without parentheses.

It's possible to treat `include` and `require` as control structures (I've seen it done), but I strongly advise not to. Treat them simply as ways to organize your code and nothing more. `goto` is a way of having control jump around a program using labels. It's also another way to glimpse into the abyss of madness. Avoid it. I'm not even going to explain it to you.

Figure 4-1. *Do. Not. Use. Goto.*
