```
// ...
function c()
{
    print_r(debug_backtrace());
}
// ...
```

... running the program again first gives the following output for `debug_backtrace()`...

```
Output:
    [0] => Array
        (
            [file] => /usr/src/myapp/debug_backtrace.php
            [line] => 14
            [function] => c
            [args] => Array
                (
                )
        )
    [1] => Array ...
```

... which is an array structure, each element of which is a sub-array with elements corresponding to useful info about the call (file, line number, function name, and even arguments).

The output of `debug_print_backtrace()` is the same data but formatted into the same string you would see if the default exception handler had generated the trace. Modify `c()` again to the following implementation...

```
// ...
function c()
{
    print debug_print_backtrace();
}
// ...
```

... and run it as before. This time we get the following familiar output:
