```
Output:
#0 /usr/src/myapp/debug_backtrace.php(14): c()
#1 /usr/src/myapp/debug_backtrace.php(6): b()
#2 /usr/src/myapp/debug_backtrace.php(27): a()
```

When objects are involved, there will be some additional indexes in the sub-arrays. I will need to jump ahead of the book again and put some object-oriented code here, but it's not much more challenging than when I showed how to make your `Exception` objects. The `class` keyword indicates a class definition, with `public function foo()` defining a method called `foo()`, which is just a function that belongs to the class.

```
class A
{
    public function doA(B $b)
    {
        $b->doB();
    }
}
class B
{
    public function doB()
    {
        print_r(debug_backtrace());
    }
}
$a = new A();
$a->doA(new B());
```

```
Output:
    [0] => Array
        (
            [file] => /usr/src/myapp/05.14_object_backtrace.php
            [line] => 7
            [function] => doB
            [class] => B
            [object] => B Object ...
            [type] => ->
            [args] => Array ...
```
