Appending New Elements

If we use the syntax from the previous example, but the brackets do not contain a key, PHP will create a new element in the array instead.

```
$myArr1 = ["Alice", "Bob"];
$myArr1[] = "Russell";
print_r($myArr1);
```

```
Output:
Array
(
    [0] => Alice
    [1] => Bob
    [2] => Russell
)
```

The keyless syntax simply tells PHP to add a new element to the end of the array and give it the next available key. We could have achieved the same results with the following code: `$myAddr[2] = "Russell;"` provided we knew what the next index value of the key was going to be.

There is also a built-in array function `array_push()` that can be used to achieve the same result.

```
$myArr1 = ["Bob", "Alice"];
array_push($myArr1, "Russell");
```

Output is not given here, but it is identical to the previous example. It is worth noting that `array_push()` is not preferred for appending single values at a time because of the slight overhead of using a function call; it is really intended for appending multiple new elements in one statement. We'll see more of this function in the section "Combining Arrays" later in the chapter.

Prepending New Elements

It is also possible to put new values at the beginning of an array using another built-in function: `array_unshift()`:
