With foreach

Probably the simplest way to execute a block of code for each element in an array is to use the language construct `foreach`. This construct requires an expression given in parentheses: `foreach (Iterable as $val)` or `foreach (Iterable as $key => $val)`. The first form will set `$val` to each element in turn on each iteration; the second form also provides the element's key (useful for associative arrays). The names of these two variables follow the same naming rules as any other PHP variable:

```
$numbers = [1, 7, 6, 9];
$total = 0;

foreach ($numbers as $v) {
    $total += $v;
}

print "average of \$numbers is " . $total / count($numbers) . "\n";

$album = [
    'title' => 'Number of the Beast',
    'artist'  => 'Iron Maiden',
    'details' => 'Work of genius',
];

foreach ($album as $k => $v) {
    print "'{$k}' has value: {$v}\n";
}

print "\$k = {$k} and \$v = {$v}\n";

Output:
average of $numbers is 5.75
'title' has value: Number of the Beast
'artist' has value: Iron Maiden
'details' has value: Work of genius
$k = details and $v = Work of genius
```

`foreach` is intuitively named: it will execute the code between the braces for every element in the `$album` array, and a full explanation of this construct can be found in Chapter 4, "Logic and Control." When we process the `$numbers` indexed array, we
