The continue statement is executed when we don't find the band we're looking for. When a continue statement is evaluated, the rest of the block is skipped, and execution continues at the beginning of the block with the next element.

Terminating Early

As well as skipping array elements, it might also be necessary to end the loop entirely. For this we use the break construct in a similar manner to continue:

```
$myArr = ['Alice', 'Bob', 'Russell', 'Rita', 'Sue'];

foreach ($myArr as $name) {
    if ($name === 'Russell') {
        // Pretend something went horribly wrong with Russell
        print "{$name} went so wrong that we can't continue :(\n";
        break;
    }

    print "{$name} is fine.\n";
}

Output:
Alice is fine.
Bob is fine.
Russell went so wrong that we can't continue :(
```

Much like continue, break stops execution of the loop block. However, rather than carrying on to the next iteration, control is returned to the main program immediately.

Traversing Multidimensional Arrays

For more complex data structures, multiple loops can be nested within each other. The outer loop works on the parent array; the inner loop works on each child of the parent:

```
$guitars = [
    ['make' => 'Ibanez', 'model' => 'RG-8570z' , 'price' => '£2100'],
    ['make' => 'Fender', 'model' => 'American Ultra Stratocaster',
    'price' => '£1800'],
];
```
