```
$name = 'Alice';
$arr = [
    'name' => 'Russell'
];
extract($arr, EXTR_PREFIX_IF_EXISTS, 'new');
print "\$name: {$name}" . PHP_EOL; // $name is untouched
print "\$new_name: {$new_name}" . PHP_EOL; // $new_name is created to avoid
                                           overwriting $name

Output:
$name: Bob
$name: Alice
$new_name: Russell
```

The code above demonstrates the default behavior of `extract()`. The extracted array contains a `name` key, which maps to an existing `$name` variable, so the variable is given a new values. When the `EXTR_PREFIX_IF_EXISTS` flag is set, the function will create a new variable using the given prefix; in this case, we specify a prefix `new`, so the new variable is `$new_name`. We can also get `extract()` to skip elements in the input array if they collide with existing variables:

```
$name = 'Alice';
$arr = [
    'name' => 'Bob',
];
extract($arr, EXTR_SKIP, 'new');
print "\$name: {$name}" . PHP_EOL;

Output:
$name: Alice
```

Here's a summary of all the possible flags for `extract()`:
