manual install of a `.rpm` file (RPM – Redhat package manager – is the tech underpinning DNF and Yum). In the following example I use Fedora 42 (installed as VM from the ISO installation file at https://download.fedoraproject.org/pub/fedora/linux/releases/42/Server/x86_64/iso/Fedora-Server-dvd-x86_64-42-1.1.iso). Find your release version number – `$ cat /etc/redhat-release` – and then use that to install the RPM file with from url https://rpms.remirepo.net/fedora/remi-release-XX.rpm

```
$ cat /etc/redhat-release
Fedora release 42 (Adams)
```

```
$ sudo dnf -y install https://rpms.remirepo.net/fedora/remi-release-42.rpm
Updating and loading repositories:
 Fedora 42 - x86_64 - Updates
 Fedora 42 openh264 (From Cisco) - x86_64
 ...
```

```
$ sudo dnf update -y
Updating and loading repositories:
 Remi's Modular repository - Fedora 42 - x86_64
 Remi's RPM repository - Fedora 42 - x86_64
 ...
```

Note that the name of the `.rpm` will vary with the version of Fedora, our examples here use release 42 so the file installed is `remi-release-42.rpm`. Now we can search the output of `dnf search --showduplicates` for the expanded list of PHP versions:

```
$ dnf search --showduplicates php | grep 'php74-php-0\|php84-php-0'
Updating and loading repositories:
