With constructor property promotion you are free to mix and match; not every variable has to be promoted. The following code is perfectly legal:

```
public function __construct(
    private $foo,
    $bar,
    private $qux
) {
    $this->doSomethingWith($bar);
}
```

Destructors

The inverse of `__construct()` is `__destruct()`, which is called when an object no longer has any references (which means there is no longer any way to access it and it becomes eligible for garbage collection) or when PHP shuts down at the end of the program lifecycle. Here's a simple demonstration:

```
class FinkBot
{
    public function __construct()
    {
        print "Let's spit on our hands and get to work." . PHP_EOL;
    }

    public function __destruct()
    {
        print "I tried to show you... something beautiful." . PHP_EOL;
    }
}

$bot = new FinkBot();
print "Welcome to Los Angeles, Mr. Fink." . PHP_EOL;

unset($bot);
print "That's all, folks." . PHP_EOL;
```
