```
    "general": "Martok",
    "major": "Kira"
}
```

There's no functional limit to the number of interfaces a class can implement, obviously system resources are theoretically exhausted at some point, but I can only imagine how big the number is. Prepare for uncomfortable questions in code reviews if you have a double-digit number of them.

Extending Interfaces

Interfaces can be extended. This means that one interface can have all the members defined in another, then implement their own on top. This feature is called *inheritance* and classes can do it too; we'll be getting to that in a moment. Any class implementing an extended interface must also implement any methods inherited from parent interfaces or suffer the consequences:

```
interface Foo
{
    public function doFoo();
}

interface Bar extends Foo
{
    public function doBar();
}

class FooBar implements Bar
{
    public function doBar()
    {
        // bar things...
    }
}
```

```
Output:
PHP Fatal error:  Class FooBar contains 1 abstract method and must therefore
be declared abstract or implement the remaining methods (Foo::doFoo) ...
```
