Parent and Child Classes

To create a parent/child inheritance relationship, we use the PHP keyword `extends`. Let's organize `QuoteBot` into a generalized parent and specialized child classes:

```
class QuoteBot
{
    protected array $quoteStash = ['', '', ''];

    public function getQuote(): string
    {
        return $this->quoteStash[rand(0,2)];
    }
}

class LebowskiBot extends QuoteBot
{
    protected array $quoteStash = [
        "Obviously, you're not a golfer." . PHP_EOL,
        "That's just, like, your opinion, man." . PHP_EOL,
        "Forget it, Donny You're out of your element." . PHP_EOL,
    ];
}

class FinkBot extends QuoteBot
{
    protected array $quoteStash = [
        "I'm a writer, you monsters! I create!" . PHP_EOL,
        "I'll show you the life of the mind!" . PHP_EOL,
        "I've always found that writing comes from a great inner pain." .
        PHP_EOL,
    ];
}
```

Here we have a parent class `QuoteBot` and two child classes of it called `LebowskiBot` and `FinkBot`. The keyword `extends` in the child class declaration tells PHP that `LebowskiBot` and `FinkBot` are children of `QuoteBot`. Note the access level of `$quoteStash` is set to `protected`. This hides the property from code outside the class but allows it to be inherited by subclasses.
