Basic Enums

```
enum Suit
{
    case CLUBS;
    case DIAMONDS;
    case HEARTS;
    case SPADES;
}

class Card
{
    public function __construct(
        private readonly Suit $suit,
        // rest of class declaration
```

We've restricted `Card::$suit` by declaring the constructor property `$suit` with the enum type `Suit`. Now we're forced to use a `Suit` enumerated case when constructing a new `Card`, rather than any old string:

```
var_dump(new Card(Suit::SPADES, 'ace'));
$card = new Card('cabbages', 'four');

Output:
object(Card)#1 (2) {
  ["suit":"Card":private]=>
  enum(Suit::SPADES)
  ["value":"Card":private]=>
  string(3) "ace"
}
Fatal error: Uncaught TypeError: Card::__construct(): Argument #1 ($suit)
must be of type Suit, string given...
```

This is safer code, and we're no longer allowed to play a four of cabbages (feel free to invent that game, it sounds like fun). There's a small drawback to enums in this form, let's see what happens when we try to use the `Card::getFullName()` method:
