```
class Bard
{
    public function __construct(
        public BardInstrument $instrument
    ) {
    }
}

var_dump(new Bard(BardInstrument::Bagpipes));
var_dump(new Bard(BardInstrument::DEFAULT));

Output:
object(Bard)#1 (1) {
  ["instrument"]=>
  enum(BardInstrument::Bagpipes)
}
object(Bard)#1 (1) {
  ["instrument"]=>
  enum(BardInstrument::Harp)
}
```

As we can see, it's perfectly fine for an enum constant to refer to one of the enum cases (and is a good use case for the feature).

Namespacing

Just as with functions and variables, classes can also be namespaced, and the syntax and rules are identical to those seen in Chapter 3, "Functions." Here's a quick recap:

```
namespace Fink {
    class QuoteBot
    {
        public static function insight(): void
        {
            print "I've always found that writing comes from a great inner
            pain." . PHP_EOL;
        }
```
