```
    }
}

namespace Lebowski {
    class QuoteBot
    {
        public static function insight(): void
        {
            print "...dude, let's go bowling." . PHP_EOL;
        }
    }
}

namespace {
    \Fink\QuoteBot::insight();
    \Lebowski\QuoteBot::insight();
}

Output:
I've always found that writing comes from a great inner pain.
...dude, let's go bowling.
```

Hopefully this should look familiar. The same caveat to multiple namespaces mentioned in Chapter 3, "Functions," applies here too. I've used multiple namespaces and placed their contents inside braces for the sake of brevity. PSR-12 coding standards dictate that only one namespace should be declared per file. The vast majority of namespaced class declarations that you encounter in the real world will look similar to the following (opening PHP tag included for reference):

```
<?php

namespace Lebowski;

class QuoteBot
{
    // rest of file
```
