```
    $magician = new Alice();
    $magician->debug();
}

Output:
Fillory\Niffin
TheRealWorld\Alice
Fillory\Niffin::debug
```

`__TRAIT__` behaves as we would expect; its value is set to the trait (and its namespace) where the declaration lives. So too is `__METHOD__`. `__CLASS__`, however, is set to where it is used (not declared), because traits are not classes. In addition to these magic constants, every class (and object) has a `::class` constant available, which returns a string value of the fully qualified name.

Object Functions

There are built-in functions designed to work with classes and objects; we've seen `spl_autoload_register()` already. Some of these functions are used to find out what classes, traits, and interfaces are available. Others will return information about specific classes or objects, a technique known as introspection.

Broadly speaking, the object functions will either tell you an object or class exists at all, tell you what an object is, or tell you what you can do with it.

Does It Exist?

```
namespace Application {
    trait SomeTrait
    {
    }

    enum SomeEnum
    {
    }
}
```
