```
$obj = new stdClass();

var_dump(get_class($obj));
var_dump(is_a($obj, 'stdClass'));
var_dump(is_a($obj, stdClass::class));

Output:
string(8) "stdClass"
bool(true)
bool(true)
```

There is also `get_called_class()`, which behaves in a similar way to late static binding to return the name of the class or object executing the function at run time:

```
class Magician
{
    public static function staticDebug(): void
    {
        var_dump(get_called_class());
    }

    public function debug(): void
    {
        var_dump(get_called_class());
    }
}

class Quentin extends Magician
{
}

$magician = new Magician();
$quentin = new Quentin();

$magician::staticDebug();
$magician->debug();
$quentin::staticDebug();
$quentin->debug();
```
