Arithmetic Operators

```
var_dump(1 + 2);
var_dump(2.1 - 1); // will cast 1 to 1.0 and return a float
var_dump('2' * '4.5'); // will cast both strings to floats and
                       return a float
var_dump(1_000_000 / 2); // special decimal integer syntax for readability
```

```
Output:
int(3)
float(1.1)
float(9)
int(500000)
```

That covers the four basic (or *radical*) mathematical operations: addition, subtraction, multiplication, and division. The final line uses a new decimal integer syntax introduced in PHP 7.4, which allows underscores, which are typically used to partition the number into thousands, like commas might be used when writing *1,000,000*.

The + and - operators can also be used to make changes to variables in the following way:

```
$intString = '12345';
$fltString = '123.4';
$num = 1;

$intString = +$intString;
$fltString = +$fltString;
$num = -$num;

var_dump($intString);
var_dump($fltString);
var_dump($num);
```

```
Output:
int(12345)
float(123.4)
int(-1)
```
