```
var_dump(1 / INF); // float(0)
var_dump(NAN * INF); // float(NAN)
var_dump(INF / NAN); // float(NAN)
```

```
Output:
float(0)
float(NAN)
float(NAN)
```

As well as numbers so big they are treated as infinite, it is possible to have numbers so infinitesimally small that they cannot be expressed as floats any more. When this happens, the value is simply changed to zero:

```
$tinyFloat = PHP_FLOAT_MIN;

var_dump($tinyFloat);
var_dump($tinyFloat / 10);
var_dump($tinyFloat / 1E3);
var_dump($tinyFloat / 1E15);
var_dump($tinyFloat / 1E16);
```

```
Output:
float(2.2250738585072014E-308)
float(2.225073858507203E-309)
float(2.225073858507E-311)
float(2.5E-323)
float(0)
```

Notice that as we accumulate values on the exponent (by dividing by powers of ten), we lose precision in the mantissa. This enables us to go beyond the limits of 10^{-308}, which might feel counter-intuitive: after all, 10^{-308} is larger than 10^{-323}. Think of `PHP_INT_MIN` as the smallest float available with maximum `PHP_FLOAT_DIG` precision.

Floating-Point Precision

Now for some fun. Take a look at this.

```
var_dump((0.1 + 0.7) * 10);
```
