As you can see, the output looks very much like that from the previous example (`random_bytes()` and `random_int()`), and that's because those functions are wrappers around the `Randomizer` class. By default, the `Randomizer` uses a crypto-secure engine to generate numbers, but others can be specified during instantiation should you want or need to:

```
// Mersenne Twister engine - NOT crypto secure
$randomizer = new \Random\Randomizer(new \Random\Engine\Mt19937());
```

Using the `Randomizer` class like this provides additional functionality over the secure functions we've already looked at:

```
var_dump($randomizer->nextInt());
var_dump($randomizer->shuffleBytes('I love random numbers'));

$arr = ['I', 'love', 'random', 'numbers'];

var_dump($randomizer->shuffleArray($arr));
$keys = $randomizer->pickArrayKeys($arr, 2);
foreach ($keys as $k) {
    print $arr[$k] . ' ';
}

Output:
int(2990379820754061450)
string(21) "eb  vemosannrd olruIm"
array(4) {
  [0]=>
  string(1) "I"
  [1]=>
  string(6) "random"
  [2]=>
  string(4) "love"
  [3]=>
  string(7) "numbers"
}
```
