```
$ docker image inspect hello-world
[
    {
        "Id": "sha256:9c7a54a9a43cca047013b82af109fe963fde787f63f9e016f
        dc3384500c2823d",
        "RepoTags": [
            "hello-world:latest"
        ],
        ...
        "ContainerConfig": {
            "Cmd": [
                "/bin/sh",
                "-c",
                "#(nop) ",
                "CMD [\"/hello\"]"
            ],
        ...
        "RootFS": {
            "Type": "layers",
            "Layers": [
                "sha256:01bb4fce3eb1b56b05adf99504dafd31907a5aadac736e36
                b27595c8b92f07f1"
            ]
        },
        ...
```

I've truncated a lot of the JSON output, but there's two config nodes worth noting here. The `RootFS` node shows that `hello-world` has a single filesystem layer, which makes sense because it is a very simple image that does a simple job. The `ContainerConfig.Cmd` node shows what will happen when a `hello-world` container starts, in this case it is a shell command: `/bin/sh -c "/hello"`. This is the heart of Docker (and containers in general): they run a process, not an entire (virtual) system.
