```
Output:
Hello $str
Hello world
```

It is also possible to use more complex variable expressions if they are wrapped in brace characters, such as array elements or object properties:

```
$array = [
    'interpolation',
    'a_key' => 'test',
];

$obj = new class
{
    public string $prop = 'String';
};

print "{$obj->prop} {$array[0]} {$array['a_key']}" . PHP_EOL;

Output:
String interpolation test
```

There are some slightly wonky rules around what you can get away with when using the complex interpolation syntax. Functions can be used, but only if they return the name of a variable (which is then interpolated); the return value itself can't be interpolated:

```
function strange(): string
{
    return 'wibble';
}

$wibble = 'an odd design choice';

print "This is {strange()}" . PHP_EOL;
print "This is {${strange()}}" . PHP_EOL;

Output:
This is {strange()}
This is an odd design choice
```
