However, object method call return data *can* be used for interpolation:

```
$obj = new class
{
    public function fine(): string
    {
        return 'And this is just fine!';
    }
};

print "{$obj->fine()}" . PHP_EOL;

Output:
And this is just fine!
```

There used to be a noticeable performance penalty with double-quoted strings in older versions of PHP, but things have improved over the years. There is still a slight overhead in both processing and memory use, though, so it's considered better practice to use double quotes only when you need their additional utility.

Special Character Escapes

Another useful feature of double-quoted strings is that they allow escape sequences. Certain special characters can be represented by a combination of a backslash character followed by a particular letter…

Table 8-1. *String letter escape sequences*

Sequence	Character
\n	linefeed LF *0x0A*
\r	carriage return CR *0x0D*
\t	horizontal tab HT *0x09*
\v	vertical tab VT *0x0B*
\e	escape ESC *0x1B*
\f	form feed FF *0x0C*
