... or symbol:

Table 8-2. *String symbol escape sequences*

Sequence	Character
\\	backslash
\$	dollar
\"	double-quote

Some of the non-printing control characters are rarely seen in the wild, but tabs and linefeeds are fairly ubiquitous. Here's a quick demo of how these escapes work:

```
$hello = "Hello world.";

print "\"Lorem ipsum\" is standard text for testing typographic
systems.\n";
print "The variable \$hello has a value of \"{$hello}\"" . PHP_EOL;
print "Vertical\vtabs\vdo\vthis. Here is a backslash: \\" . PHP_EOL;

Output:
"Lorem ipsum" is standard text for testing typographic systems.
The variable $hello has a value of "Hello world."
Vertical
        tabs
            do
              this. Here is a backslash: \
```

Note that the first line of output uses a single `\n` linefeed character; on Linux (or similar) systems and any web browser, this will move the cursor to the next line, but on Windows systems it does not: Windows has historically used `\r\n` characters to denote a line ending in text. (This is why I have used the built-in constant `PHP_EOL` throughout this book, because it will always produce the correct line endings for the platform the code runs on – more to come on string constants shortly.)
