Unicode Escape Sequences

The final type of escape sequence is the Unicode escape. This takes the form `"\u{N}"` where `N` is the hexadecimal Unicode code point of the desired character. This chapter has an entire section devoted to the fascinating (well, to some of us) history of character encoding in computing, a multi-decade journey that has led to the Unicode system, which is ubiquitous across the entire internet. For now, here's a very quick demonstration:

```
print "I hope this works... \u{1F4A5}" . PHP_EOL;
print "Unicode is a superset of ASCII.\u{0A}This proves it\u{21}" .
PHP_EOL;
```

```
Output:
I hope this works... 💥
Unicode is a superset of ASCII.
This proves it!
```

Here we've used three Unicode code unit values: *0x1F4A5* ("Collision Symbol"), *0x0A* ("Line Feed"), and *0x21* ("Exclamation Mark"). Whether or not you see the collision symbol depends on your system's encoding settings and fonts, but the other two are identical to the ASCII code points (a deliberate design choice) and will not cause any issues (unless you're using something exotic from 1980s Japan). Lots more to come on this soon.

Heredoc and Nowdoc

For larger string literal character sequences that might become cumbersome to express with quotes, PHP supports the multi-line *heredoc* syntax:

```
$heredoc = <<<IDENTIFIER
Lorem ipsum dolor sit amet, consectetur adipiscing elit, sed
do eiusmod tempor incididunt ut labore et dolore magna aliqua.
IDENTIFIER;

print $heredoc . PHP_EOL;
```
