```
    [2] => Array
        (
            [0] => bread
            [1] => apples
        )

)
```

In a similar way to character classes, sub-patterns also have a few specific metacharacters (or metacharacters that behave differently in a sub-pattern context, if you prefer) that control the way they behave. Beginning a sub-pattern with `(?:` disables capturing, and modifiers (that would normally go after the closing pattern delimiter) can be inserted to enforce the modified behavior within the sub-pattern, for example, `(?i:` would force a sub-pattern match to be case insensitive. If modified behavior is required in a capturing sub-pattern, the beginning syntax is `((?i)`, and here's an example to demonstrate:

```
$text = 'bRoWn BrEaD, gReEn aPpLeS, oRanGe eR... OrAnGeS';
preg_match_all('/(?i:brown|green) ((?i)bread|apples)/', $text, $matches);
print_r($matches);
```

```
Output:
Array
(
    [0] => Array
        (
            [0] => bRoWn BrEaD
            [1] => gReEn aPpLeS
        )

    [1] => Array
        (
            [0] => BrEaD
            [1] => aPpLeS
        )

)
```
