preg_grep()

This is a straightforward function that accepts a single regex pattern, an array of sample strings, and an optional flag parameter to control behavior. Each sample string in the array is checked for a match against the pattern and added to a new array, which is then returned.

```
$text = [
    'Iron Maiden - Somewhere in Time',
    'Iron Maiden - Powerslave',
    'Metallica - Master of Puppets'
];
print_r(preg_grep('/Iron Maiden/', $text));
```

```
Output:
Array
(
    [0] => Iron Maiden - Somewhere in Time
    [1] => Iron Maiden - Powerslave
)
```

The logic can be inverted to return non-matching strings by passing the constant `PREG_GREP_INVERT`:

```
print_r(preg_grep('/Iron Maiden/', $text, PREG_GREP_INVERT));
```

```
Output:
Array
(
    [2] => Metallica - Master of Puppets
)
```

Notice that the array keys are retained in the results.

preg_match(), preg_match_all()

We've seen these functions used throughout this section, so you already know that `preg_match()` returns only the first match, and `preg_match_all()` will return all matches (an implicit 'global' modifier). There's some additional functionality to be aware
