```
Output:
string(19) "2024-11-19 00:00:00"
string(19) "2024-11-17 12:00:00"
```

It is also possible to instantiate `DateTime` with a timestamp integer value, using a special string format:

```
$dt = new DateTime('@1725148800');
print $dt->format('Y-m-d H:i:s');
```

```
Output:
2024-09-01 00:00:00
```

Formatting Output

By now you've probably realized that `DateTime::format()` is the go-to method for building strings intended for human-readable output. The year, month, day, hour, minute, second, and even milli- and microseconds have multiple ways that they can be expressed, and not all elements of the date and time need to be output. In addition, the time zone name, or UTC offset, can also be included in the output. Here are a few examples for dates:

```
$dt = new DateTime('01-SEP-2024');
// year
print $dt->format('Y y') . PHP_EOL;
// month
print $dt->format('F M m n') . PHP_EOL;
// day
print $dt->format('l D d j jS');
```

```
Output:
2024 24
September Sep 09 9
Sunday Sun 01 1 1st
```
