```
    [sunset] => 1725417397
    [transit] => 1725394122
    [civil_twilight_begin] => 1725369325
    [civil_twilight_end] => 1725418919
    ...
```

As you can see, all time-related data in and out of this function is a Unix timestamp. There are two functions – `date_sunrise()`, and `date_sunset()` – which are deprecated in PHP 8 (and will generate an error if called) but work in the same way as `date_sun_info()`.

getdate(), gettimeofday(), localtime()

`getdate()` works in two ways depending on how it is called (either with no arguments or an integer Unix timestamp) and returns an array of data, which are the date/time component values:

```
print_r(getdate(1725148800));
```

```
Output:
Array
(
    ...
    [mon] => 9
    [year] => 2024
    [yday] => 244
    [weekday] => Sunday
    [month] => September
    [0] => 1725148800
)
```

```
print_r(getdate());
```

```
Output:
    [seconds] => 42
    [minutes] => 18
    [hours] => 14
```
