```
    minute: null,   // defaults to 47
    second: 0,      // overrides 25
    month: null,    // defaults to 01
    day: null,      // defaults to 03
    year: 2001      // overrides 2025
);

print date($format, $tstamp);
```

```
Output:
2001-01-03 00:47:00
```

`mktime()` will happily handle out-of-range values and negative values too, which makes it quite versatile when combining dates and times with arithmetic. Negative values count backwards from the previous next-largest unit; for example, an `hour` value of `-1` will be calculated as `23:00` hours of the previous day…

```
$tstamp = mktime(
    hour: -1,
    day: 10,
);
print date('d H', $tstamp);
```

```
Output:
09 23
```

… a `minute` value of `-10` will be calculated as the fiftieth minute of the previous hour:

```
$tstamp = mktime(
    hour: 12,
    minute: -10,
);
print date('H:i', $tstamp);
```

```
Output:
11:50
```

Likewise, positive values that exceed the maximum for the field will increment the next highest unit:
