Traits

If you remember from Chapter 6, "Object Fundamentals," traits offered a way to mitigate PHP's single inheritance model. There is no specific representation of traits in the UML, but it could be approximated with a stereotyped parent class.

Association

So far, we've seen how to describe inheritance and implementation with the UML, but this is only one way in which objects in a system can be related. Another form of relationship is *association*. An association arises when a class property is used to refer to instances of other classes.

It's safe to assume that an instance of `Shop` will need some way to communicate with an `Inventory` object; the simplest way would be to store a reference to `Inventory`, and so we have our first association type.
