```
  string(3) "bar"
  ["cow"]=>
  string(3) "moo"
}
```

You'll see that `$_GET` contains our query data, all neatly parsed into an associative array (please note the URL argument to the `curl` command is enclosed in quotes because most shells will treat the `&` as a special character). It is also possible to give structure to query string data, using familiar-looking array syntax:

```
$ curl 'http://localhost:8080/index.php?animals[]=cat&animals[]=dog'
array(1) {
  ["animals"]=>
  array(2) {
    [0]=>
    string(3) "cat"
    [1]=>
    string(3) "dog"
  }
}
```

... and even associative arrays (make sure to add `-g` to the curl command to avoid a parsing error by the curl binary):

```
$ curl -g 'http://localhost:8080/index.php?animals[feline]=cat&animals[ca
nine]=dog'
array(1) {
  ["animals"]=>
  array(2) {
    ["feline"]=>
    string(3) "cat"
    ["canine"]=>
    string(3) "dog"
  }
}
```
