You can also parse raw query strings in PHP (available via `$_SERVER['QUERY_STRING']`). Using the `parse_str()` built-in function, the resulting associative array is identical to the one created for `$_GET`, but you must pass in a variable as a second argument to capture it (I've no idea why it can't just return an array; the older parts of PHP are just like that sometimes):

```
parse_str('animals[]=cat&animals[]=dog', $queryData); // second param
                                                      is by-ref
var_dump($queryData);
```

```
Output:
array(1) {
  ["animals"]=>
  array(2) {
    [0]=>
    string(3) "cat"
    [1]=>
    string(3) "dog"
  }
}
```

Request (Body) Data

All of the query string examples above were made as `GET` requests (the curl command's default HTTP method if not passing a `-X` option). Query strings will also work just as well with `POST` and `PUT`. The following commands…

```
$ curl -X 'POST' http://localhost:8080/index.php?foo=bar
$ curl -X 'PUT' http://localhost:8080/index.php?foo=bar
```

… will produce the same output:

```
array(1) {
  ["foo"]=>
  string(3) "bar"
}
```
