```
    <meta charset="utf-8" />
    <title>The easiest page you'll ever create</title>
  </head>
  <body>
      <h1>Lorem ipsum dolor sit amet</h1>
      <p>consectetur adipiscing elit</p>
  </body>
</html>
EOS;
```

You can check the results in a web browser if you like, via `http://localhost:8080/index.php`

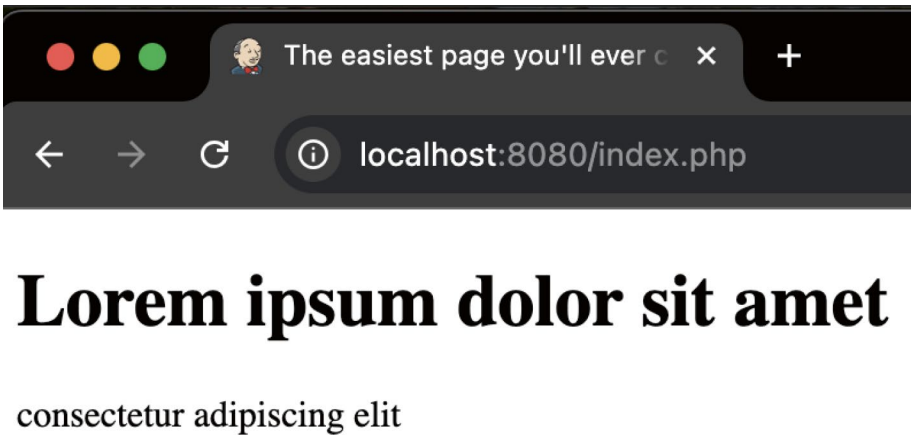

Figure 11-3. *A simple page*

Getting response body data to the client is super easy, but this code isn't particularly useful. You don't need PHP to just echo out a static document; a static HTML file would be faster and less effort. Real applications will be full of logic and data interpolation, building the final content dynamically. Now let's add some string interpolation to our example:

```
$mainPara = '<p>consectetur adipiscing elit</p>';
print <<< EOS
<!DOCTYPE html>
```
