The usual PHP type-casting rules apply. If you were to attempt to interpolate `$object` into a string with `"blah #{object} blah"` then that object would need to implement the `Stringable` interface (possess a `__toString()` method).

Mathematics

The Twig mathematical operators are identical to their PHP counterparts, with a tiny sprinkle of syntactic sugar in one case:

Table 11-31. *Twig mathematical operators*

+	Addition
-	Subtraction
/	Divide
*	Multiply
%	Modulus
//	Floored integer result of a division (like calling `round(x / y)`)
**	Exponentiation (`x ** y` raises x to the power y)

Again, PHP type coercion is at work here; see Chapter 7, "Numbers," for the rules and pitfalls.

Logical

Here, Twig opts for words rather than symbols such as && or ||...
