Twig Inheritance

Twig also features an inheritance mechanism, whereby a common base template can have units called *blocks* defined, which the inheriting child templates will override. Blocks can be empty or have default content placed inside them. The `{% extends %}` tag tells the templating engine that the current template is a child; the parent is then fetched and rendered, with child blocks overriding the parent blocks.

Extending a Template

Let's define a very simple parent template…

```
{# views/parent.html.twig #}
<!DOCTYPE html>
<html>
  <head>
    {% block titleEle %}
      <title>BASE</title>
    {% endblock %}
  </head>
  <body>
    {% block bodyContent %}{% endblock %}
  </body>
</html>
```

… and a child template that extends it:

```
{# views/child.html.twig #}
{% extends 'parent.html.twig' %}

{% block titleEle %}
  <title>CHILD</title>
{% endblock %}

{% block bodyContent %}
  <div>CHILD CONTENT HERE...</div>
{% endblock %}
```
