Appendix A

Chapter 1, "Getting Started," introduced the PSR-12 PHP coding standard and mentioned two tools for enforcing standards and fixing any issues that might be found, and these were PHPCodeSniffer's `phpcs` and `phpcbf` utilities. This appendix concerns their installation and use. CodeSniffer can be installed by downloading the `.phar` single-file archive: a PHAR – PHP Archive – is a self-contained distribution of PHP code and other assets, and a bootstrap file that instructs your system to run the PHAR contents using your PHP CLI binary.

```
$ curl -OL https://squizlabs.github.io/PHP_CodeSniffer/phpcs.phar
$ sudo mv ./phpcs.phar /usr/local/bin/phpcs
$ sudo chmod +x /usr/local/bin/phpcs
$ which phpcs
/usr/local/bin/phpcs
```

Doing it this way means that you will likely also need to install some additional PHP system packages, because `phpcs` needs the `tokenizer`, `xmlwriter`, and `SimpleXML` PHP extensions to function. If running `phpcs` reports an error along the lines of "Please enable xmlwriter and SimpleXML," then you'll need to install those extensions (`apt-get install -y php-tokenizer php-xml` or equivalent).

In addition, `phpcs` can usually be installed via your system's package manager:

Debian

```
$ apt-cache search phpcs
php-codesniffer - PHP, CSS and JavaScript coding standard analyzer
and checker
```

```
$ sudo apt-get install -y php-codesniffer
Reading package lists... Done
...
```
