Summary

Throughout this chapter, you've been working on making your app more secure by setting up a solid authentication and authorization system. You started by integrating Laravel Breeze to set up a secure user authentication flow, which included configuring login, registration, and password reset functionalities using pre-built views and controllers. Then, you moved on to implementing RBAC by creating custom middleware that verified user roles, making sure that sensitive routes were accessible only to authorized users.

Next, you added more authentication features by using Laravel Socialite to integrate social logins, so users could sign in with their preferred social media accounts. You finally decided to step up security by setting up two-factor authentication using Laravel Fortify. This meant adding the necessary columns to the users table, updating the user model with the right trait, and changing Fortify's configuration to enable 2FA features. It's a pretty straightforward process: you get the user credentials, make sure the sessions are secure, and set up a solid access control system. All of this together boosts the security of your application.
